Conclusions

What in common?

- Map Coloring Problems,
- Cryptarithmic Problems,
- Scheduling Problems,
- Timetable Design Problems,
- Configuration Problems (hardware, software),
- Radio Frequency Assignment,
- Crossword Puzzles,
- Sudoku,
- Einstein or Zebra Problem.

SEND + MORE = MONEY

What in common?

- SEND+MORE=MONEY,
- Variables: S, E, N, D, M, O, R, Y.
- Domains: $\{0, 1, 2, 3, 4, 5, 6, 7, 8, 9\}$,
- All variables are different,
- $S \neq 0, M \neq 0$,
- All constraints must be satisfied.

Characteristic Features

- only the **final solution** counts (no path to it),
- there can be 0, 1 or many solutions (all are equivalent),
- **strong combinatorial explosion**.

Australia — Map Colouring Problem

- **Variables:** WA, NT, Q, NSW, V, SA, T ;
- **Domains:** $D_i = \{red, green, blue\}$;
- **Constraints:** adjacent regions must have different colors e.g., $WA \neq NT$ (if the language allows this), or $(WA, NT) \in \{(red, green), (red, blue), (green, red), (green, blue), \dots\}$.

Australia — Map Coloring Problem Solution

Solutions are assignments satisfying all constraints, e.g.,
{WA = red, NT = green, Q = red, NSW = green, V = red, SA = blue, T = green}

Tools - Constraint Graph

CSP

GEIST

Constraint Graph — represents constraints

- variables \rightarrow nodes,
- binary constraints \rightarrow arcs.

Conclusions

Varieties of CSPs

Discrete variables

- Boolean CSPs, incl. Boolean satisfiability (NP-complete) infinite domains (integers, strings, etc.)
- job scheduling, variables are start/end days for each job,
- need a *constraint language*, e.g., $StartJob_1 + 5 \leq StartJob_3$,
- *linear* constraints solvable, *nonlinear* undecidable.

Continuous variables

- e.g., start/end times for Hubble Telescope observations,
- linear constraints solvable in poly time by LP methods.

Problem: Combinatorial Explosion!

Potential solutions number = $card(D_1 \times D_2 \times \dots \times D_n)$

Computational complexity = $O(d^n)$

Problem Structure

Exploring problem
structure

Conclusions

Typical types of constraints

- **Unary** constraints involve a single variable, e.g.

$$SA \neq \textit{green},$$

- **Binary** constraints involve pairs of variables, e.g.

$$SA \neq WA,$$

- **Higher-order** constraints involve 3 or more variables, e.g. cryptarithmic column constraints of the form

$$Z = \textit{mod}(X + Y + C), \quad C' = \textit{carry}(X + Y + C)$$

- **Preferences** (soft constraints), e.g., *red* is better than *green* often representable by a cost for each variable assignment
→ constrained optimization problems.

Conclusions

Example: Cryptarithmic

A simple example

$$\begin{array}{r} \text{TWO} \\ + \text{TWO} \\ \hline \text{FOUR} \end{array}$$

(a)

- Variables: $F T U W R O X_1 X_2 X_3$
- Domains: $\{0, 1, 2, 3, 4, 5, 6, 7, 8, 9\}$
- Constraints: $alldiff(F, T, U, W, R, O)$
 $O + O = R + 10 \cdot X_1$, etc.

Example Application Areas

- Assignment problems
e.g., who teaches what class?,
- Timetabling problems
e.g., which class is offered when and where?,
- Hardware configuration,
- Spreadsheets,
- Transportation scheduling,
- Factory scheduling,
- Floorplanning,
- Scheduling Problems,
- Timetable Design Problems,
- Configuration Problems (e.g. Renault Megane Case),
- Radio Frequency Assignment,
- Packing problems,
- Layout problems.

Conclusions

CSP: Definition

CSP statement

- $X = \{X_1, X_2, \dots, X_n\}$ — a set of variables,
- $D = \{D_1, D_2, \dots, D_n\}$ — their domains,
- $C = \{(S_i, R_i) : i = 1, 2, \dots, n\}$ — constraints,
 - S_i — scope — a selection of variables,
 - R_i — relation defined over Cartesian Product of domains appropriate for the scope variables,

CSP solution

A solution to CSP given by (X, D, C) is any assignment of values to variables of X of the form

$$\{X_1 = d_1, X_2 = d_2, \dots, X_n = d_n\},$$

such that $d_i \in D_i$, and for any constraint in $(S_i, R_i) \in C$, R_i is satisfied by the appropriate projection of the solution vector (d_1, d_2, \dots, d_n) over variables of S_i .

Standard Search Formulation (incremental)

Basic approach

States are defined by the values assigned so far:

- **Initial state**: the empty assignment, \emptyset ,
 - **Successor function**: assign a value to an unassigned variable that does not conflict with current assignment,
 - \implies fail if no legal assignments (not fixable!),
 - **Goal test**: the current assignment is complete and consistent, i.e.
 - **Consistency'**: all the constraints are satisfied.
- 1 This is the same for all CSPs!
 - 2 Every solution appears at depth n with n variables,
 - 3 \implies use depth-first search (DFS),
 - 4 Path is irrelevant, so can also use complete-state formulation,
 - 5 $b = (n - \ell)d$ at depth ℓ , hence $n!d^n$ leaves!!!

Backtracking Search

Commutative variable assignment

Variable assignments are *commutative*, i.e.,

$WA = red$ then $NT = green$ same as $NT = green$ then $WA = red$

Search

- Only need to consider assignments to a single variable at each node,
- $\implies b = d$ and there are d^n leaves,
- Depth-first search for CSPs with single-variable assignments is called *backtracking search*
- Backtracking search is the basic uninformed algorithm for CSPs,
- Can solve n -queens for $n \approx 25$.

Conclusions

Improving Backtracking Efficiency

What can be improved?

General-purpose methods can give huge gains in speed:

- 1 Which variable should be assigned next?
- 2 In what order should its values be tried?
- 3 Can we detect inevitable failure early?
- 4 Can we take advantage of problem structure?

MVR: Minimum Remaining Values

MVR heuristic (MCV: Most Constrained Variable)

- choose the variable with the *fewest* legal values

Example

Search

Real Worls CSPs

Formal Stuff

Backtracking
search

Improving
backtracking search:
heuristics

Problem Structure

Exploring problem
structure

Conclusions

Tie-breaker among MRV variables

- choose the variable with the *most constraints* on remaining variables

Example

LCR: Least Constraining Value

LCR heuristic

- given a variable, choose the least constraining value: the one that rules out the fewest values in the remaining variables

Example

These simple heuristics makes 1000 queens feasible!

Forward Checking

FC idea

- keep track of remaining legal values for unassigned variables,
- terminate search when any variable has no legal values.

Conclusions

Constraint Propagation

Forward checking limitations

- forward checking propagates information from assigned to unassigned variables,
- but does not provide early detection for all failures:

Example

Hidden problem

- *NT* and *SA* cannot both be blue!
- *Constraint propagation* repeatedly enforces constraints locally

Conclusions

Arc Consistency

AC idea

Simplest form of propagation makes each arc **consistent**

- $X \rightarrow Y$ is consistent iff
for every value $x \in X$ there is *some* allowed $y \in Y$

Example

AC Tips

- If X loses a value, neighbors of X need to be rechecked.
- Arc consistency detects failure earlier than forward checking.
- Can be run as a preprocessor or after each assignment.

Arc Consistency

Problem Structure

Exploring problem
structure

Conclusions

Problem decomposition

- Problem decomposition is always a good idea!
- Separated problems are better than overlapping ones!
- Many small problems are better than few but bigger!

Some hints

- Suppose each subproblem has c variables out of n total.
- Worst-case solution cost is $n/c \cdot d^c$, *linear* in n

E.g., $n = 80$, $d = 2$, $c = 20$

$2^{80} = 4$ billion years at 10 million nodes/sec

$4 \cdot 2^{20} = 0.4$ seconds at 10 million nodes/sec

Tree-structured CSPs

Example

A theorem for trees

Theorem: if the constraint graph has no loops, the CSP can be solved in $O(nd^2)$ time.

Compare to general CSPs, where worst-case time is $O(d^n)$

This property also applies to logical and probabilistic reasoning: an important example of the relation between syntactic restrictions and the complexity of reasoning.

Algorithm for tree-structured CSPs

Algorithm outline

- 1 Choose a variable as root, order variables from root to leaves such that every node's parent precedes it in the ordering.

- 2 For j from n down to 2, apply $Arc\text{-}Consistency(Parent(X_j), X_j)$.
- 3 For j from 1 to n , assign X_j consistently with $Parent(X_j)$.

Nearly tree-structured CSPs

Conditioning

Conditioning: instantiate a variable, prune its neighbors' domains.

Example

Cutset conditioning

Cutset conditioning: instantiate (in all ways) a set of variables such that the remaining constraint graph is a tree

Cutset size $c \implies$ runtime $O(d^c \cdot (n - c)d^2)$, very fast for small c .

Problem Structure

Exploring problem
structure

Conclusions

Iterative procedures

- Hill-climbing, simulated annealing typically work with “complete” states, i.e., all variables assigned;
- To apply to CSPs:
allow states with unsatisfied constraints operators *reassign* variable values;
- Variable selection: randomly select any conflicted variable;
- Value selection by *min-conflicts* heuristic:
choose value that violates the fewest constraints i.e., hillclimb with $h(n) = \text{total number of violated constraints}$.

Example: 4-Queens

4-queens

- **States:** 4 queens in 4 columns ($4^4 = 256$ states).
- **Operators:** move queen in column.
- **Goal test:** no attacks.
- **Evaluation:** $h(n) =$ number of attacks.

Performance of min-conflicts

- Given random initial state, can solve n -queens in almost constant time for arbitrary n with high probability (e.g., $n = 10,000,000$)
- The same appears to be true for any randomly-generated CSP *except* in a narrow range of the ratio

$$R = \frac{\text{number of constraints}}{\text{number of variables}}$$

Conclusions

Final Remarks

In summary:

- 1 CSPs are a special kind of problem:
 - states defined by values of a fixed set of variables
 - goal test defined by *constraints* on variable values.
- 2 Backtracking = depth-first search with one variable assigned per node.
- 3 Variable ordering and value selection heuristics help significantly.
- 4 Forward checking prevents assignments that guarantee later failure.
- 5 Constraint propagation (e.g., arc consistency) does additional work to constrain values and detect inconsistencies.
- 6 The CSP representation allows analysis of problem structure.
- 7 Tree-structured CSPs can be solved in linear time.
- 8 Iterative min-conflicts is usually effective in practice.
