|---|---|---|--|---|---|
|---|---|---|--|---|---|

What is the smallest number that can be represented in this format?

| 0 | 0 | 0 | 0 | 0 |
|---|---|---|---|---|
|   |   |   |   |   |

What is the largest number that can be represented in this format?

| 9 | 9 | 9 | 9 | 9 |
|---|---|---|---|---|

Numerical Methods - Lecture 2

# Why represent numbers in floating point format?

• Example 2. How a number 256.78 can be represented using 5-places?

rounded off

chopped

Conclusion: The error is smaller than 0.01

Numerical Methods - Lecture 2

2

### **Calculation of errors**

True Error

$$|x-x_o|$$

accurate or true value of  $x_0$ 

Relative True Error  $\frac{\left|x-x_{o}\right|}{x_{o}}$ 

Calculations:

$$\varepsilon_t = \frac{\left| x - x_o \right|}{x_o} \times 100\% = \frac{\left| 256.79 - 256.786 \right|}{256.786} \times 100\% = 0.001558\%$$

Numerical Methods - Lecture 2

### **Calculation of errors**

### Relative errors of small numbers are large.

Compare:

$$\varepsilon_t = \frac{|x - x_o|}{x_o} \times 100\% = \frac{|256.79 - 256.786|}{256.786} \times 100\% = 0.001558\%$$

$$\varepsilon_t = \frac{|x - x_o|}{x_o} \times 100\% = \frac{|3.55 - 3.546|}{3.546} \times 100\% = 0.11280\%$$

Absolute true errors are the same:

$$|x - x_o| = |256.786 - 256.79| = |3.546 - 3.55| = 0.004$$

Numerical Methods - Lecture 2

-

# How to keep relative true errors at a costant level?

The number can be represented as:

sign x mantissa x 10 exponent

or

sign x mantissa x 2 exponent

256.78 is written as 
$$+2.5678\times10^{2}$$
  
0.003678 is written as  $+3.678\times10^{-3}$   
 $-256.78$  is written as  $-2.5678\times10^{2}$ 

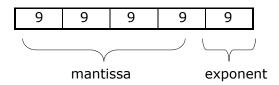

Numerical Methods - Lecture 2

What do we gain by using the floating point representation?

# The rage of the numbers that can be expressed has increased

If we use only 5 places to represent a positive number with a positive exponent, the smallest number that can be expressed is 1 and the largest is  $9.999\cdot10^9$ 

The range of numbers that can be represented has increased from 999.99 to  $9.999 \cdot 10^9$ .

Numerical Methods - Lecture 2

-

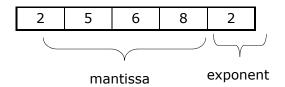

What do we lose by using a floating point representation?

### **Precision**

Why?

The umber 256.78 will be represented as  $2.5678 \cdot 10^2$  on five places:

There will be a round-off error.

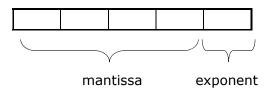

Numerical Methods - Lecture 2

Q

# **Example for an individual study**

1. Write down the number 576329.78 on five places in a similar manner that discussed in the previous example:

- 2. Calculate the true error and the relative true error of round off
- 3. Compare the results with the previous example (256.78).

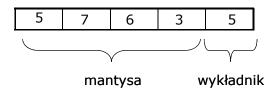

Numerical Methods - Lecture 2

0

# Solution of the example

1. The number 576329.78 written on five places is:

- 2. The true error is 29.78 and the relative true error is 0.0051672%
- 3. For the number 256.78 these errors are: 0.02 (smaller) and 0.0077888% (comparable)

Numerical Methods - Lecture 2

 $\sigma \times m \times 10^e$ 

sign(-1 or +1)

mantissa  $(1)_{10} \le m < (10)_{10}$ 

an integer exponent

Example

 $\sigma = -1$ 

 $-2.5678 \times 10^{2}$ 

m = 2.5678

e = 2

# Floating point arithmetic - binary representation

Form of a number

an integer exponent

 $\sigma \times m \times 2^{\epsilon}$ 

sign (0 – positive or 1 - negative)

exponent  $(1)_2 \le m < (2)_2$ 

Example:

 $\sigma = 0$ 

 $(1.1011011)_2 \times 2^{(101)_2}$ 

m = 1011011

e = 101

1 is not represented

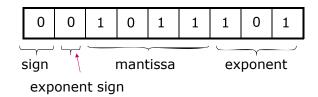

Numerical Methods - Lecture 2

# **Example for an individual study**

We have 9-bits

- •first bit represents the sign of the number,
- second bit represents the sign of the exponent,
- •the next four bits represent the mantissa,
- •the last three bits represent the exponent

Find the number (in decimal), which is presented above

Numerical Methods - Lecture

15

### **Solution**

$$(54.75)_{10} = (110110.11)_2 = (1.1011011)_2 \times 2^5$$
  

$$\cong (1.1011)_2 \times (101)_2$$

is not represented

 $(54)_{10}$ 

Numerical Methods - Lecture 2

### What is the accuracy ε?

For each digital machine epsilon  $\epsilon$  is defined as a parameter determining the accuracy of the calculations:

$$\epsilon = N^{-t}$$

where: N=2 (in binary), N=10 (in decimal), t is the number of bits representing the mantissa

 $\boldsymbol{\epsilon}$  is the lower, when more bits are allocated to represent the mantissa  $\boldsymbol{M}$ 

Epsilon  $\epsilon$  can be regarded as a parameter characterizing the accuracy of the computing machine (the smaller the  $\epsilon$  the more accurate are the calculations).

Double precession (Fortran)  $\epsilon_{DP} = \epsilon^2$ 

Numerical Methods - Lecture 2

4 =

# What is the accuracy ε?

Epsilon  $\epsilon$  is the smallest number that when added to 1.000 produces a number that can be represented as different from 1.000.

exponent sign

$$\in_{mach} = 1.0625 - 1 = 2^{-4}$$

Numerical Methods - Lecture 2

16

 $x = M \times N^w$ 

# Single precision in IEEE-754 format (Institute of Electrical and Electronics Engineers)

32 bits for single precision

sign (s) exponent (e') mantissa (m)

*Number* = 
$$(-1)^s \times (1 \cdot m)_2 \times 2^{e'-127}$$

Numerical Methods - Lecture 2

17

### Example

Sign

Biased

Mantissa (m)

(s) Exponent (e')

Value = 
$$(-1)^s \times (1.m)_2 \times 2^{e^t-127}$$
  
=  $(-1)^1 \times (1.10100000)_2 \times 2^{(10100010)_2-127}$   
=  $(-1) \times (1.625) \times 2^{162-127}$   
=  $(-1) \times (1.625) \times 2^{35} = -5.5834 \times 10^{10}$ 

Numerical Methods - Lecture 2

# The exponent for the 32-bit IEEE -754 standard

8-bit exponent means

$$0 \le e' \le 255$$

The fixed exponent shift is 127 and therefore

$$-127 \le e \le 128$$

In fact, 
$$1 \le e' \le 254$$

Numbers e' = 0 and e' = 255 are reserved for special cases

Exponent range  $-126 \le e \le 127$ 

# **Representation of special numbers**

$$e' = 0$$
 — all zeros

$$e' = 255$$
 — all ones

| S      | e'    | m       | Represents |
|--------|-------|---------|------------|
| 0      | zeros | zeros   | 0          |
| 1      | zeros | zeros   | -0         |
| 0      | ones  | zeros   | $\infty$   |
| 1      | ones  | zeros   | $-\infty$  |
| 0 or 1 | ones  | nonzero | NaN        |

### IEEE-754 Format

The largest number

$$(1.1.....1)_2 \times 2^{127} = 3.40 \times 10^{38}$$

The smallest number

$$(1.00.....0)_2 \times 2^{-126} = 2.18 \times 10^{-38}$$

**Epsilon** 

$$\varepsilon_{mach} = 2^{-23} = 1.19 \times 10^{-7}$$

Met.Numer, wykład :

---

### **Analysis of errors**

If we do not know the exact value of  $x_0$  we calculate the approximate error as the difference in the values obtained in the consecutive approximations:

$$x_n - x_{n-1}$$

Relative error  $\varepsilon_a$ :

$$\varepsilon_a = \frac{x_n - x_{n-1}}{x_n}$$

Numerical Methods - Lecture 2

# **Example**

For 
$$f(x) = 7e^{0.5x}$$
 in  $x = 2$  find

a) 
$$f'(2)$$
 for  $h = 0.3$ 

b) 
$$f'(2)$$
 for  $h = 0.15$ 

c) approximate error

### Solution

$$f'(x) \approx \frac{f(x+h) - f(x)}{h}$$

a) 
$$h = 0.3$$

$$f'(2) \approx \frac{f(2+0.3) - f(2)}{0.3} = \frac{7e^{0.5(2.3)} - 7e^{0.5(2)}}{0.3} = 10,265$$

Numerical Methods - Lecture

22

# **Example** (cont.)

b) 
$$h = 0.15$$

$$f'(2) \approx \frac{f(2+0.15) - f(2)}{0.15} = \frac{7e^{0.5(2.15)} - 7e^{0.5(2)}}{0.15} = 9,880$$

c) 
$$\varepsilon_a = \frac{x_n - x_{n-1}}{x_n}$$

$$\varepsilon_a = \frac{9,880 - 10,265}{9,8800} \approx -0,0389$$

Error 3,89%

Numerical Methods - Lecture 2

# The relative error as a criterion for ending the iterative procedure

If the relative error is less than or equal to a predetermined number then further iterations are no longer required

$$|\varepsilon_a| \leq \varepsilon_s$$

If we require at least m significant digits in the result then

$$|\varepsilon_a| \le 0.5 \times 10^{2-m}$$

Numerical Methods - Lecture

\_\_

# Relative error and significant digits

$$|\varepsilon_a| \le 0.5 \times 10^{2-m}$$

| h     | f'(2)  | $ \epsilon_a $ | m |       |
|-------|--------|----------------|---|-------|
| 0.3   | 10.265 | N/A            | 0 |       |
| 0.15  | 9.8800 | 0.03894        | 3 |       |
| 0.10  | 9.7559 | 0.01271        | 3 | 0,05  |
| 0.01  | 9.5378 | 0.02286        | 3 |       |
| 0.001 | 9.5164 | 0.00225        | 4 | 0,005 |

The exact value is 9.514

Numerical Methods - Lecture 2

## Sources of errors in numerical calculations

- 1. Input errors (input data errors)
- 2. Truncation error
- 3. Round off error

Input errors occur when the input data entered into the computer memory are different from the exact values.

Truncation errors are errors due to numerical procedures caused by reducing the number of operations.

Round off errors are errors that usually can not be avoided. They arise in the course of the calculations, and can be reduced by setting skillfully the method and sequence of tasks.

Numerical Methods - Lecture 2

27

# **Input errors**

Sources of input errors:

- the input data are the result of measurement of physical quantities
- a finite length of binary words and therefore prerounding is needed
- preliminary rounding of irrational numbers

**Rounding of numbers** that cannot be expressed exactly is accomplished by:

- chopping
- rounding off

Numerical Methods - Lecture 2

# **Example:**

$$\pi \approx 3,1415$$
 9265359  $\pi \approx 3,1415$   $\pi \approx 3,1416$ 

chopping

rounding off

Rounding off introduces smaller error than chopping.

Numerical Methods - Lecture

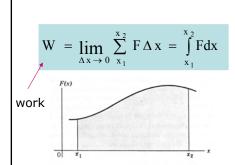

20

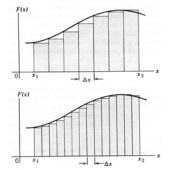

# **Truncation error**

Caused by the use of the approximate formula instead of a full mathematical operation:

- when calculating the sum of the infinite series
- when calculating integral, derivative

Numerical Methods - Lecture 2

## **Taylor series**

If the function is continuous and all derivatives f', f'', ... fn exist within the interval [x, x + h] the value of the function at the point x + h can be calculated as:

$$f(x+h) = f(x) + f'(x)h + \frac{f''(x)}{2!}h^2 + \frac{f'''(x)}{3!}h^3 + \cdots$$

The Maclaurin series is simply the Taylor series about the point x=0

$$f(0+h) = f(0) + f'(0)h + f''(0)\frac{h^2}{2!} + f'''(0)\frac{h^3}{3!} + \dots +$$

Numerical Methods - Lecture 2

2.

# **Examples**

Some examples of Taylor series which you must have seen

$$\cos(x) = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \cdots$$

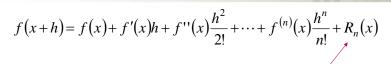

$$\sin(x) = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \cdots$$

$$e^x = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \cdots$$

Numerical Methods - Lecture 2

## Truncation error in the Taylor series

remainder

$$R_n(x) = \frac{h^{n+1}}{(n+1)!} f^{(n+1)}(c)$$

$$x < c < x + h$$

# **Example**

The Taylor series for  $e^x$  at point x=0 is given by

$$e^x = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \frac{x^4}{4!} + \frac{x^5}{5!} + \cdots$$

It can be seen that as the number of terms used increases, the error decreases and hence a better estimate can be found.

Question: How many terms would it require to get an approximation of e1 within a magnitude of true error of less than 10-6?

$$e^{1} = 1 + 1 + \frac{1^{2}}{2!} + \frac{1^{3}}{3!} + \frac{1^{4}}{4!} + \frac{1^{5}}{5!} + \cdots$$
$$\approx 2 + \frac{1}{2} + \frac{1}{6} + \frac{1}{24} + \frac{1}{120}$$

### **Solution**

$$x = 0, h = 1, f(x) = e^{x}$$
  $R_n(x) = \frac{h^{n+1}}{(n+1)!} f^{(n+1)}(c)$ 

$$R_n(0) = \frac{1^{n+1}}{(n+1)!} f^{(n+1)}(c)$$

since

$$= \frac{(1)^{n+1}}{(n+1)!} e^{c}$$

$$x < c < x + h$$
$$0 < c < 0 + 1$$
$$0 < c < 1$$

$$\frac{1}{(n+1)!} < |R_n(0)| < \frac{e}{(n+1)!}$$

Numerical Methods - Lecture

3 E

### **Solution**

$$\frac{e}{(n+1)!} < 10^{-6}$$
 true error

$$(n+1)! > 10^6 e$$

$$(n+1)! > 10^6 \times 3$$

$$n \ge 9$$

It means that 9 terms or more are needed to get a true error less than  $10^{-6}$ 

Numerical Methods - Lecture

### **Arithmetic operations**

### 1. Addition and subtraction

To add or subtract two standard floating-point number, the exponents should be made equal with an adequate shift of the mantissa.

**Example:** Add  $0,4546 \cdot 10^5$  to  $0,5433 \cdot 10^7$ 

shift

 $0,0045\cdot10^{7}+0,5433\cdot10^{7}=0,5478\cdot10^{7}$ 

Solution: We loose some significant digits

Numerical Methods - Lecture 2

27

# **Arithmetic operations**

## 2. Multiplication

**Example:** Multiply 0,5543·10<sup>12</sup> by 0,4111·10<sup>-15</sup>

Multiply mantissas and add the exponents.

 $0,5543 \cdot 10^{12} \cdot 0,4111 \cdot 10^{-15} = 0,2278273 \cdot 10^{-3} = 0,2278 \cdot 10^{-3}$ 

### 3. Division

**Example:** Divide  $0,1000 \cdot 10^5$  by  $0,9999 \cdot 10^3$ 

 $0,1000\cdot10^{5}/0,9999\cdot10^{3}=0,1000\cdot10^{2}$ 

All the time we loose some significant digits which is the source of the error

Numerical Methods - Lecture 2

# **Sequence of operations**

 $(a+b)-c\neq(a-c)+b$  lack of associativity

a(b-c) ≠(ab-ac) lack of distributive property

**Example:** 
$$a = 0.5665 \cdot 10^{1}$$
,  $b = 0.5556 \cdot 10^{-1}$ ,  $c = 0.5644 \cdot 10^{1}$ 

$$(a+b)=0,5665\cdot10^{1}+0,5556\cdot10^{-1}$$

$$=0,5665\cdot10^{1}+0,0055\cdot10^{1}=0,5720\cdot10^{1}$$

$$(a+b)-c=0,5720\cdot10^{1}-0,5644\cdot10^{1}=0,7600\cdot10^{-1}$$

$$(a-c)=0.5665\cdot10^{1}-0.5644\cdot10^{1}=0.0021\cdot10^{1}=0.2100\cdot10^{-1}$$

$$(a-c)+b=0,2100\cdot10^{-1}+0,5556\cdot10^{-1}=0,7656\cdot10^{-1}$$

Numerical Methods - Lecture

--

### Wilkinson Lemma

Rounding off errors occurring during floating point operations are equivalent to substitution of accurate numbers by slightly perturbed numbers on which we act exactly.

For individual arithmetical operations:

$$fl(x_1 \pm x_2) = x_1(1 + \varepsilon_1) \pm x_2(1 + \varepsilon_2)$$

$$fl(x_1 \cdot x_2) = x_1(1 + \varepsilon_3) \cdot x_2 = x_1 \cdot x_2(1 + \varepsilon_3)$$

 $fl(x_1/x_2) = x_1(1+\varepsilon_4)/x_2 = x_1/(x_2(1+\varepsilon_5))$ 

symbol of operation performed on floating-point data

and

 $\varepsilon_i \leq \varepsilon$ 

Numerical Methods - Lecture 2

# **Arithmetic operations**

Instead of interpreting the error as a result of rounding (chopping) that occurred during scaling (changing the exponent) of the components, it can be assumed according to Wilkinson Lemma that the action was taken exactly (without error), but on slightly changed data.

In the addition example:  $0,4546\cdot10^5+0,5433\cdot10^7$ 

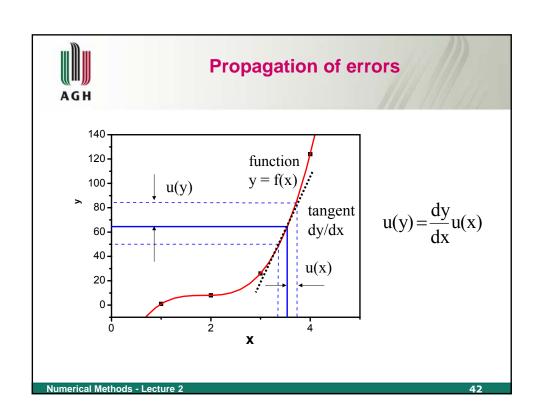

Exact result: 0,547846 · 107

Approximate result: 0,5478·10<sup>7</sup>

Relative error of the sum: 0.00008 is less than  $\epsilon=10^{-4}$ 

The same result is obtained when we add 0,4546  $\cdot 10^5$  and 0,543254  $\cdot 10^7$ 

Numerical Methods - Lecture 2

### **Total derivative method**

For  $y=f(x_1,x_2,...x_n)$  where maximum uncertainties  $\Delta x_1$ ,  $\Delta x_2$ , ...  $\Delta x_n$  are small compared with the values of the variables  $x_1,x_2,$  ...  $x_n$  the <u>maximum uncertainty</u> of y can be expressed as:

$$\Delta y = \left| \frac{\partial y}{\partial x_1} \right| \Delta x_1 + \left| \frac{\partial y}{\partial x_2} \right| \Delta x_2 + \dots + \left| \frac{\partial y}{\partial x_n} \right| \Delta x_n$$

Numerical Methods - Lecture 2

13

### **Example**

Estimate the uncertainty of density  $\rho$  of a ball of mass m and radius R

$$\rho(m,R) = \frac{m}{(4/3)\pi R^3}$$

absolute error

$$\Delta \rho = \left| \frac{\partial \rho}{\partial m} \right| \Delta m + \left| \frac{\partial \rho}{\partial R} \right| \Delta R$$

but 
$$\frac{\partial \rho}{\partial m} = \frac{1}{(4/3)\pi R^3}$$
  $\frac{\partial \rho}{\partial R} = \frac{-3m}{(4/3)\pi R^4}$ 

relative error

$$\varepsilon_{\rho} = \varepsilon_m + 3\varepsilon_R$$

Numerical Methods - Lecture 2

### **Errors of arithmetic operations**

### **Addition**

$$A = a \pm \Delta a \qquad B = b \pm \Delta b$$

absolute errors

$$A + B = a + b \pm \Delta a \pm \Delta b = a + b \pm \Delta (a + b)$$

the addition absolute error

Therefore, the addition (subtraction) absolute error is equal to the sum of absolute errors of components.

$$\Delta(a \pm b) = \Delta a + \Delta b$$

### **Errors of arithmetic operations**

the addition relative error 
$$\varepsilon_{a+b} = \frac{\Delta a + \Delta b}{a+b}$$
 the subtraction relative error 
$$\varepsilon_{a-b} = \frac{\Delta a + \Delta b}{a+b}$$

$$\varepsilon_{a-b} = \frac{\Delta a + \Delta b}{a-b}$$

Subtraction relative error can be large even if the relative errors of minuend and subtrahend are small. Subtracting of nearly equal numbers should be avoided!

This phenomenon is called **reduction** of significant digits

It is important for the calculation of Newton's difference quotients approximating derivatives of functions, roots of a quadratic equation with the dominant factor of the first power, etc.

Numerical Methods - Lecture 2

# The concept of zero

We lose the precise meaning of the number 0 if we perform numerical calculations

$$x^2 + 2x - 2 = 0$$

Exact roots are

$$-1\pm\sqrt{3}$$

Approximate solutions

Verify that upon substitution of the approximate solutions to  $x^2+2x-2$  you will not get 0!!!

You should therefore avoid subtraction and the loop condition should not be set to "zero",

Numerical Methods - Lecture 2

47

### **Useful hints:**

In the numerical calculations it is advantageous:

- To solve the same problem by another method, or by the same method, but with a different order of operations
- To solve the problem on slightly perturbed input data

Numerical Methods - Lecture 2

## Tragic example of the rounding off error

On February 25th, 1991 in Dhahran, Saudi Arabia, 28 American soldiers were killed in the attack of the Iraqi Scud missiles. The defense system Patriot did not detect any assault. Why?

The system calculates the area, which should be scanned based on the speed of the object and the last detection. The internal clock was set to measure every 1/10 second and 24-bit word length was assumed. Due to rounding off, the absolute error was  $9.5 \ 10^{-8}$  s which after 100 hours amounted to:

$$9.5 \cdot 10^{-8} \times 10 \times 60 \times 60 \times 100 = 0.34 \text{ sec}$$

Based on this, the calculated displacement is 687 m. Object is considered outside the range when the displacement is 137 m

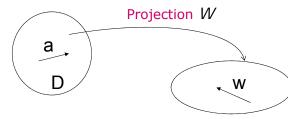

Numerical Methods - Lecture 2

40

## Tasks and numerical algorithms

- Numerical task requires a clear and unambiguous description of the functional relationship between the input or "independent variables" of the task and output data, i.e. searched results.
- Numerical task is a problem determining the results vector  $\overrightarrow{\mathbf{w}}$  on the basis of data vector  $\overrightarrow{\mathbf{a}}$

task well-defined

 $\vec{\mathbf{w}} = W(\vec{\mathbf{a}})$ 

unambiguous assignment

Numerical Methods - Lecture 2

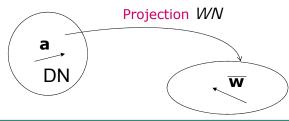

### Tasks and numerical algorithms

- Numerical algorithm is a full description of the operations correctly transforming the input data vector to the vector output data.
- The algorithm is formulated correctly when the number of necessary actions is be finite

Resulting vector depends on the computing accuracy  $\varepsilon$  of the machine

**Numerical Methods - Lecture 2** 

E1

# **Examples of algorithms**

Given a complex number a=x+iy. Calculate 1/a<sup>2</sup>

Algorithm I:

1. t = y/x (tangent phase of number a)

$$2. \ \left|a\right|^2 = x^2 + y^2 \quad \text{(module of number a)}$$

3. 
$$\operatorname{Re}\left(\frac{1}{a^2}\right) = \frac{1}{|a|^2} \frac{1-t^2}{1+t^2}$$
  $\operatorname{Im}\left(\frac{1}{a^2}\right) = \frac{1}{|a|^2} \frac{-2t^2}{1+t^2}$ 

The task is well-defined if:

$$x^2 + y^2 \neq 0$$

that is: 
$$D = R^2 - \{(0,0)\}$$

This algorithm is formulated correctly (11 necessary steps)

Numerical Methods - Lecture 2

### **Examples of algorithms**

Not for each data pair  $(x, y) \neq 0$  the solution to the problem can be found using the algorithm I.

- 1. There will be an overflow of floating point numbers (for x = 0, also because of rounding to zero)
- 2. The overflow may happen even in the first step when
- $x = 10^{-25}$  and  $y = 10^{25}$  because of the division y / x
- 3. For x = 0, and  $y \ne 0$  the solution cannot be determined using this algorithm. The increase in the accuracy of the calculation does not change this fact.

Algorithm I is not numerically stable

Numerical Methods - Lecture

F-6

# **Examples of algorithms**

Given a complex number a=x+iy. Calculate  $1/a^2$ 

Algorithm II:

1. 
$$r = \text{Re}\left(\frac{1}{a^2}\right) = \frac{x^2 - y^2}{x^2 + y^2}$$

2. 
$$u = \text{Im}\left(\frac{1}{a^2}\right) = \frac{-2xy}{x^2 + y^2}$$

Algorithm II is formulated correctly (9 necessary steps)

Algorithm II is numerically stable due to the continuity of equations for  $x^2 + y^2 \neq 0$ 

Numerical Methods - Lecture 2

### **Conditioning and stability**

The calculation algorithm is numerically stable if for any selected data vector

$$a_0 \in D$$

there exists an accuracy of the calculations  $\epsilon_0$ , that for  $\epsilon < \epsilon_0$  we have

$$a_0 \in DN(\varepsilon)$$

and

$$\lim_{\varepsilon \to 0} WN(\boldsymbol{a}_0, \varepsilon) = W(\boldsymbol{a}_0)$$

The algorithm is numerically stable when increasing the accuracy of the calculations any existing solution to the problem can be found.

Numerical Methods - Lecture 2

5.5

# **Conditioning and stability**

Due to the rounding off error

$$WN(\boldsymbol{a}, \varepsilon) \neq W(\boldsymbol{a})$$

By Lemma of Wilkinson disturbed data vector can be selected

$$a + \delta a \in D$$

ror which  $WN(a, \varepsilon) = W(a + \delta a)$ 

Size of the distortion  $\delta a$  depends on:

- -the data vector **a**
- -the number of performed operations
- -the accuracy of calculations

Numerical Methods - Lecture 2

### **Conditioning and stability**

Based on Wilkinson's Lemma:

$$\frac{\|\delta a\|}{\|a\|} \to 0$$

when  $\varepsilon \rightarrow 0$ 

Conditioning tells us how much the result of the disturbed vector data differs from the exact result for vector data that is:

$$W(a + \delta a)$$
  $W(a)$ 

Indicator of conditions task B(a) is the number for which the following condition is satisfied:

$$\frac{\|\delta w\|}{\|w\|} \le B(a) \frac{\|\delta a\|}{\|a\|} \qquad \delta w = WN(a, \varepsilon) - W(a)$$

### Indicator of conditions task

· Let us assume the relative error size of x

$$\frac{x-\widetilde{x}}{\widetilde{r}}$$

• The relative error size f(x)

$$\frac{f(x) - f(\widetilde{x})}{f(\widetilde{x})} \approx \frac{f'(\widetilde{x})(x - \widetilde{x})}{f(\widetilde{x})}$$

· Indicator of conditions task:

$$\frac{\widetilde{x}f'(\widetilde{x})}{f(\widetilde{x})}$$

Numerical Methods - Lecture 2

### Indicator of conditions task

• Example

$$f(x) = \sqrt{x}$$

· Indicator of conditions:

$$\frac{\widetilde{x}f'(\widetilde{x})}{f(\widetilde{x})} = \frac{x\frac{1}{2\sqrt{x}}}{\sqrt{x}} = \frac{1}{2}$$

task well conditioned

EC

# Indicator of conditions task

Example

$$f(x) = \frac{10}{1 - x^2}$$

• Indicator of conditions :

$$\frac{\widetilde{x}f'(\widetilde{x})}{f(\widetilde{x})} = \frac{2x^2}{\left|1 - x^2\right|}$$

ill-conditioned task near x=1 i x=-1
